# Use quotation marks for defining string "Michael Jackson" Out[1]: 'Michael Jackson' We can also use single quotation marks: # Use single quotation marks for defining string 'Michael Jackson' Out[2]: 'Michael Jackson' A string can be a combination of spaces and digits: # Digitals and spaces in string '1 2 3 4 5 6 ' Out[3]: '1 2 3 4 5 6 ' A string can also be a combination of special characters : # Special characters in string In [4]: '@#2 #]&\*^%\$**'** Out[4]: '@#2\_#]&\*^%\$' We can print our string using the print statement: In [5]: # Print the string print("hello!") hello! We can bind or assign a string to another variable: In [6]: # Assign string to variable name = "Michael Jackson" name 'Michael Jackson' Indexing It is helpful to think of a string as an ordered sequence. Each element in the sequence can be accessed using an index represented by the array of numbers: Name= "Michael Jackson" h C a e C S 0 n а 3 5 11 12 1 2 9 10 14 0 4 6 The first index can be accessed as follows: [Tip]: Because indexing starts at 0, it means the first index is on the index 0. # Print the first element in the string print(name[0]) We can access index 6: In [8]: # Print the element on index 6 in the string print(name[6]) Moreover, we can access the 13th index: In [9]: # Print the element on the 13th index in the string print(name[13]) **Negative Indexing** We can also use negative indexing with strings: Name= "Michael Jackson" k C e C S 0 n -15 | -14 | -13 -12 -11 -10 -9 -8 -7 -6 -5 -4 -2 -3 -1 Negative index can help us to count the element from the end of the string. The last element is given by the index -1: # Print the last element in the string print(name[-1]) The first element can be obtained by index -15: # Print the first element in the string print(name[-15]) We can find the number of characters in a string by using len, short for length: # Find the length of string len("Michael Jackson") Out[12]: 15 Slicing We can obtain multiple characters from a string using slicing, we can obtain the 0 to 4th and 8th to the 12th element: Name= "Michael Jackson" h K C a e C S 0 n а

[Tip]: When taking the slice, the first number means the index (start at 0), and the second number means the length from the index to

the last element you want (start at 1)

C

1

name[::2]

name[0:5:2]

statement

Out[17]: 'Michael Jacksonis the best'

In [18]: # Print the string for 3 times

3 \* "Michael Jackson"

name = "Michael Jackson"
name = name + " is the best"

**Escape Sequences** 

Out[19]: 'Michael Jackson is the best'

In [20]: # New line escape sequence

Michael Jackson is the best

Michael Jackson

In [22]: # Include back slash in string

In [21]: # Tab escape sequence

In [19]: # Concatenate strings

name

Concatenate Strings

# Concatenate two strings

statement = name + "is the best"

'Michael JacksonMichael JacksonMichael Jackson'

from Michael Jackson to "Michael Jackson is the best".

print(" Michael Jackson \n is the best" )

print(" Michael Jackson \t is the best" )

print(" Michael Jackson \\ is the best" )

print(r" Michael Jackson \ is the best" )

a = "Thriller is the sixth studio album"

before upper: Thriller is the sixth studio album After upper: THRILLER IS THE SIXTH STUDIO ALBUM

is the best

If you want to place a back slash in your string, use a double back slash:

We can also place an "r" before the string to display the backslash:

In [23]: # r will tell python that string will be display as raw string

# Convert all the characters in string to upper case

Similarly, back slash "t" represents a tab:

Michael Jackson \ is the best

Michael Jackson \ is the best

**String Operations** 

print("before upper:", a)

print("After upper:", b)

a = "Michael Jackson is the best"
b = a.replace('Michael', 'Janet')

sequence. We can find the sub-string jack or el.

operations on the data.

b = a.upper()

Out[25]: 'Janet Jackson is the best'

C

name = "Michael Jackson"

In [27]: # Find the substring in the string.

name.find('Jasdfasdasdf')

**Change Log** 

YOU ARE WRONG

Convert the variable f to uppercase:

print(e[::2])

Print out a backslash:

print(r" \ ")

correct

In [34]:

d = "ABCDEFG"
print(d[0:3])

ABC

a = "1"
print(a)

b = "2"
print(b)

c = a + b print(c)

In [28]: # If cannot find the substring in the string

h

3

a

Name.find('el'):5

e

5

What is the value of the variable a after the following code is executed?

What is the value of the variable b after the following code is executed?

# Write your code below and press Shift+Enter to execute

What is the value of the variable c after the following code is executed?

# Write your code below and press Shift+Enter to execute

Consider the variable d use slicing to print out the first three elements:

# Write your code below and press Shift+Enter to execute

Use a stride value of 2 to print out every second character of the string e:

# Write your code below and press Shift+Enter to execute

# Write your code below and press Shift+Enter to execute

# Write your code below and press Shift+Enter to execute

Consider the variable g, and find the first index of the sub-string snow:

# Write your code below and press Shift+Enter to execute

# Write your code below and press Shift+Enter to execute

2020-11-11

2020-08-26

Everywhere that Mary went The lamb was sure to go"

In the variable g, replace the sub-string Mary with Bob:

g = "Mary had a little lamb Little lamb, little lamb Mary had a little lamb \
Its fleece was white as snow And everywhere that Mary went Mary went, Mary went \

Congratulations, you have completed your first lesson and hands-on lab in Python. However, there is one more thing you need to do. The Data Science community encourages sharing work. The best way to share and showcase your work is to share it on GitHub. By sharing your notebook on GitHub you are not only building your reputation with fellow data scientists, but you can also show it off when applying for a job. Even though this was your first piece of work, it is never too early to start building good habits. So, please read and follow this article

**Change Description** 

Updated variable names to lowercase

Moved lab to course repo in GitLab

e

5

6

# Get every second element. The elments on index 1, 3, 5 ...

# Get every second element in the range from index 0 to index 4

three. The result is a new string, and this new string consists of three copies of the original string:

name[0:4]

name[8:12]

Stride

Out[13]: 'Mich'

Out[14]: 'Jack'

In [14]:

# Take the slice on variable name with only index 0 to index 3

# Take the slice on variable name with only index 8 to index 11

We can also input a stride value as follows, with the '2' indicating that we are selecting every second variable:

8

9

We can also incorporate slicing with the stride. In this case, we select the first five elements and then use the stride:

We can concatenate or combine strings by using the addition symbols, and the result is a new string that is a combination of both:

To replicate values of a string we simply multiply the string by the number of times we would like to replicate it. In this case, the number is

You can create a new string by setting it to the original variable. Concatenated with a new string, the result is a new string that changes

Back slashes represent the beginning of escape sequences. Escape sequences represent strings that may be difficult to input. For example,

There are many string operation methods in Python that can be used to manipulate the data. We are going to use some basic string

The method replace replaces a segment of the string, i.e. a substring with a new string. We input the part of the string we would like to

change. The second argument is what we would like to exchange the segment with, and the result is a new string with the segment

The method find finds a sub-string. The argument is the substring you would like to find, and the output is the first index of the

а

9

If the sub-string is not in the string then the output is a negative one. For example, the string 'Jasdfasdasdf' is not a substring:

C

10

Name.find('Jack'):8

# Find the substring in the string. Only the index of the first elment of substring in string will be the outpl

S

11 12

0

n

14

In [25]: # Replace the old substring with the new target substring is the segment has been found in the string

Name= "Michael Jackson"

Let's try with the method upper; this method converts lower case characters to upper case characters:

back slash "n" represents a new line. The output is given by a new line after the back slash "n" is encountered:

C

10

O

13

12

Name= "Michael Jackson"
